Package 'fuzzySim'

October 4, 2023

Type Package

Title Fuzzy Similarity in Species Distributions

Version 4.10.5

Date 2023-10-04

Author Barbosa A.M.

Maintainer A. Marcia Barbosa <ana.marcia.barbosa@gmail.com>

Imports graphics, methods, modEvA (> 3.9), stats, utils

Suggests aod, parallel, raster, terra, tools

Description Functions to compute fuzzy versions of species occurrence patterns based on presence-absence data (including inverse distance interpolation, trend surface analysis, and prevalence-independent favourability obtained from probability of presence), as well as pair-wise fuzzy similarity (based on fuzzy logic versions of commonly used similarity indices) among those occurrence patterns. Includes also functions for model consensus and comparison (overlap and fuzzy similarity, loss or gain), and for data preparation, such as obtaining unique abbreviations of species names, cleaning and gridding (thinning) point occurrence data onto raster maps, selecting absences under specified criteria, converting species lists (long format) to presence-absence tables (wide format), transposing part of a data frame, selecting relevant variables for models, assessing the false discovery rate, or analysing and dealing with multicollinearity. Initially described in Barbosa (2015) <doi:10.1111/2041-210X.12372>.

Examples

```
data(rotifers)

head(rotifers)

# add column with species name abbreviations:

rotifers$spcode <- spCodes(rotifers$species, sep.species = "_",
nchar.gen = 1, nchar.sp = 5, nchar.ssp = 0)

head(rotifers)
```

```
# convert species list (long format) to presence-absence table
# (wide format):

rotifers.presabs <- splist2presabs(rotifers, sites.col = "TDWG4",
sp.col = "spcode", keep.n = FALSE)

head(rotifers.presabs)

# get 3rd-degree spatial trend surface for some species distributions:

data(rotif.env)

names(rotif.env)

rotifers.tsa <- multTSA(rotif.env, sp.cols = 18:20,
coord.cols = c("Longitude", "Latitude"), id.col = 1)

head(rotifers.tsa)

# get inverse squared distance to presence for each species:

rotifers.isqd <- distPres(rotif.env, sp.cols = 18:20,
coord.cols = c("Longitude", "Latitude"), id.col = 1, p = 2, inv = TRUE)

head(rotifers.isqd)

# get prevalence-independent environmental favourability models
# for each species:

data(rotif.env)

names(rotif.env)

rotifers.fav <- multGLM(data = rotif.env, sp.cols = 18:20,
var.cols = 5:17, id.col = 1, step = FALSE, trim = TRUE,
Favourability = TRUE)

# get matrix of fuzzy similarity between species distributions:

# either based on inverse squared distance to presence:
rot.fuz.sim.mat <- simMat(rotifers.isqd[ , -1], method = "Jaccard")

# or on environmental favourability for presence:
rot.fuz.sim.mat <- simMat(rotifers.fav$predictions[ , 5:7],
method = "Jaccard")

head(rot.fuz.sim.mat)
```

```
# transpose fuzzy rotifer distribution data to compare
# regional species composition rather than species' distributions:

names(rotifers.isqd)

rot.fuz.reg <- transpose(rotifers.fav$predictions, sp.cols = 5:7,
reg.names = 1)

head(rot.fuz.reg)

# get matrix of fuzzy similarity between (some) regions'
# species compositions:

reg.fuz.sim.mat <- simMat(rot.fuz.reg[ , 1:10], method = "Jaccard")

head(reg.fuz.sim.mat)
```

---

appendData	*Append data*

Description

This function appends the rows of a dataframe 'data2' at the bottom of another dataframe 'data1', using the values in the columns with matching names, and (optionally, by default) filling missing columns with NAs.

Usage

```
appendData(data1, data2, fill = TRUE, add.source = TRUE)
```

Arguments

data1	object inheriting class 'data.frame' to which to append data.
data2	object inheriting class 'data.frame' to append to 'data1', with column names matching those of the corresponding columns in 'data1'.
fill	logical, whether the result should keep all columns of 'data1' that are missing in 'data2', filling them with NAs in the rows with no data. The default is TRUE. If set to FALSE, the result will keep only the columns of 'data1' that are also present in 'data2'.
add.source	logical, whether the result should include an additional column saying from which input data frame ('data1' or 'data2') each row came.

Details

This function is asymmetric, i.e. appendData(data1,data2) may output different columns from appendData(data2,data1). 'data1' dictates the columns the result will have. Columns of 'data2' that are not matched in 'data1' are not kept in the output.

Value

This function returns a data frame with all the columns and rows of 'data1', extended with the rows of 'data2' with its values for the columns with matching names in 'data1'. By default, with 'add.source = TRUE', there is also an additional column specifying the source input object. If 'fill' is set to FALSE, the result only carries the columns with matching names in both data frames.

Examples

```
df1 = data.frame(A = 3:1, B = letters[1:3], C = c(1, 0, 1))
df2 = data.frame(A = 4:5, B = letters[5:4])

appendData(df1, df2)

appendData(df1, df2, fill = FALSE)
```

---

bioThreat	*Biotic threat of a stronger over a weaker species based on their favourability values*

Description

This function takes two vectors of [Fav](ourability) values at different localities for, respectively, a stronger and a weaker species (e.g., a superior vs. an inferior competitor, or an invasive predator vs. an unadapted native prey), and calculates the level of threat that the former may potentially pose to the latter in each locality.

Usage

```
bioThreat(strong_F, weak_F, character = FALSE, ...)
```

Arguments

strong_F	a numeric vector of favourability values (obtained, e.g., with functions [Fav](#) or [multGLM](#)) for the stronger species.
weak_F	a numeric vector of favourability values for the weaker species. Must be of the same lenght and in the same order as 'strong_F'.
character	logical value indicating whether the result should be returned in character rather numeric form. Defaults to FALSE.
...	additional arguments to pass to [favClass](#), namely the breaks for separating favourability values into low, intermediate and high (see Details).

Details

Based on the notion of "favorableness" by Richerson & Lum (1980), according to which competing species may or may not be able to coexist depending on their relative environmental fitnesses, Acevedo et al. (2010, 2012) and some subsequent studies (e.g. Romero et al. 2014, Munoz et al. 2015, Chamorro et al. 2019) proposed possible biotic interaction outcomes of different combinations of favourability values for two species. Favourability has the advantage, in contrast with other types of potential distribution metrics, of being directly comparable among diferent species, independently of their relative occurrence frequencies (see `Fav`). This function builds on those proposals by including additional possible combinations of higher, intermediate or low favourability values (following Munoz & Real 2006), producing the following classification of biotic threat across a set of analysed localities:

0 ('grey'): areas where favourability is low for at least one of the species (abiotic exclusion), so biotic threat does not apply.

1 ('green'): areas where favourability is high for both species, so they should both be able to thrive and therefore co-occur (sympatric coexistence), hence biotic threat is low.

2 ('yellow'): areas where favourability is high for the weaker species and intermediate for the stronger species, so the level of threat is moderate.

3 ('orange'): areas where favourability is intermediate for both species, so the stronger one potentially prevails and the level of threat is high.

4 ('red'): areas where favourability is high for the stronger species and intermediate for the weaker species, in which case the level of threat is very high (biotic exclusion).

Value

This function returns either an integer or a character vector (following the 'character' argument, which is set to FALSE by default) of the same length as 'strong_F' and 'weak_F', classifying each locality with the level of biotic threat posed by the former on the latter (see Details).

cleanCoords   *Clean coordinates*

Description

This function takes a data frame with species occurrences and removes the rows whose coordinates
do not pass a set of user-specified filters (see Arguments). Row names are inheritted from the input
data frame, i.e. if row "2" is cleaned out, output rownames will be c("1", "3", ...).

Usage

```
cleanCoords(data, coord.cols = NULL, uncert.col = NULL, abs.col = NULL,
year.col = NULL, rm.dup = !is.null(coord.cols),
rm.equal = !is.null(coord.cols),    rm.imposs = !is.null(coord.cols),
rm.missing.any = !is.null(coord.cols), rm.missing.both = !is.null(coord.cols),
rm.zero.any = !is.null(coord.cols), rm.zero.both = !is.null(coord.cols),
rm.imprec.any = !is.null(coord.cols), rm.imprec.both = !is.null(coord.cols),
imprec.digits = 0, rm.uncert = !is.null(uncert.col), uncert.limit = 50000,
uncert.na.pass = TRUE, rm.abs = !is.null(abs.col), year.min = NULL,
year.na.pass = TRUE, plot = TRUE)
```

Arguments

`data`	an object inheriting class 'data.frame' with the spatial coordinates to be cleaned, or a 'SpatVector' of points.
`coord.cols`	character or integer vector of length 2, with either the names or the positions of the columns that contain the spatial coordinates in 'data' - in this order, LONGitude and LATitude, or x and y. Can be left NULL if 'data' is a 'SpatVector', in which case the coordinates will be extracted with terra::crds().
`uncert.col`	character or integer vector of length 1, with either the name or the position of the column that reports spatial uncertainty in 'data' (e.g., in GBIF this column is usually named "coordinateUncertaintyInMeters").
`abs.col`	character or integer vector of length 1, with either the name or the position of the column that specifies whether the species is present or absent (e.g., in GBIF this column is usually named "occurrenceStatus").
`year.col`	character or integer vector of length 1, with either the name or the position of the column that specifies the year in which the observation was made (e.g., in GBIF this column is usually named "year").
`rm.dup`	logical, whether to remove rows with exactly the same pair of coordinates. The default is TRUE if 'coord.cols' is not NULL, and FALSE otherwise.
`rm.equal`	logical, whether to remove rows with exactly the same pair of coordinates, i.e. where latitude = longitude. The default is TRUE if 'coord.cols' is not NULL, and FALSE otherwise.
`rm.imposs`	logical, whether to remove rows with coordinates outside planet Earth, i.e. with absolute value >180 for longitude or >90 for latitude. The default is TRUE if 'coord.cols' is not NULL, and FALSE otherwise. Note that this is only valid for unprojected angular coordinates in geographic degrees.
`rm.missing.any`	logical, whether to remove rows where at least one of the coordinates is NA. The default is TRUE if 'coord.cols' is not NULL, and FALSE otherwise.
`rm.missing.both`	
	logical, whether to remove rows where both coordinates are NA. The default is TRUE if 'coord.cols' is not NULL and FALSE otherwise, but it is not used (as it is redundant) if rm.missing.any=TRUE.
`rm.zero.any`	logical, whether to remove rows where at least one of the coordinates equals zero (which is often an error). The default is TRUE if 'coord.cols' is not NULL, and FALSE otherwise.
`rm.zero.both`	logical, whether to remove rows where both coordinates equal zero (which is often an error). The default is TRUE if 'coord.cols' is not NULL and FALSE otherwise, but it is not used (as it is redundant) if rm.zero.any=TRUE.
`rm.imprec.any`	logical, whether to remove rows where at least one of the coordinates is imprecise, i.e. has no more decimal places than 'imprec.digits'. The default is TRUE if 'coord.cols' is not NULL and FALSE otherwise, but note this is normally only relevant for unprojected geographical coordinates in degrees; if your coordinates are in meters, they are usually precise enough without decimal places, so you should probably set this argument and the next to FALSE.

rm.imprec.both   logical, whether to remove rows where both coordinates are imprecise, i.e. have
                 no more decimal places than 'imprec.digits'. The default is TRUE if 'coord.cols'
                 is not NULL and FALSE otherwise, but it is not used (as it is redundant) if
                 rm.imprec.any=TRUE. See 'rm.imprec.any' above for important details.

imprec.digits   integer, maximum number of digits to consider that a coordinate is imprecise.
                 Used only if 'rm.imprec.any' or 'rm.imprec.both' is TRUE. The default is 0, for
                 eliminating coordinates with no more than zero decimal places.

rm.uncert   logical, whether to remove rows where the value in 'uncert.col' is higher than
                 'uncert.limit'. The default is TRUE if 'uncert.col' is not NULL, and FALSE
                 otherwise.

uncert.limit   lnumeric, threshold value for 'uncert.col'. If rm.uncert=TRUE and 'uncert.col'
                 is provided, rows with values above this will be excluded. The default is 50,000,
                 i.e. 50 km if the values in 'uncert.col' are in meters.

uncert.na.pass   logical, whether rows with NA in 'uncert.col' should be kept as having no un-
                 certainty. The default is TRUE.

rm.abs   logical, whether to remove rows where the value in 'abs.col' is (case-insensitive)
                 'absent'. The default is TRUE if 'abs.col' is not NULL, and FALSE otherwise.

year.min   positive integer specifying the minimum (earliest) value admitted for the year
                 column. The default is NULL (no limit).

year.na.pass   logical, whether rows with NA in 'year.col' should be kept as if fulfilling the
                 year.min criterion. The default is TRUE.

plot   logical value specifying whether to plot the result. The default is TRUE.

Details

This function applies some basic cleaning procedures for species occurrence data, removing some of
the most common mistakes in biodiversity databases. It is inspired by a few functions (namely 'co-
ord_incomplete', 'coord_imprecise', 'coord_impossible', 'coord_unlikely' and 'coord_uncertain')
that were present in the 'scrubr' package by Scott Chamberlain, which was archived (https://github.com/ropensci-
archive/scrubr).

Value

This function returns a data frame of the input 'data' (or a spatial data frame of class 'SpatVector'
if this matches the input) without the rows that met the specified removal criteria. The row names
match the original ones in 'data', at least if 'data' is of class 'data.frame'. Messages are displayed
in the console saying how many rows passed each removal filter. If plot=TRUE (the default), a plot
is also displayed with the selected points (blue dots) and the excluded points (red "x").

---

corSelect   *Select among correlated variables based on a given criterion*

Description

This function computes pairwise correlations among the variables in a dataset and, among each pair of variables correlated above a given threshold(or, optionally, below a given significance value), it excludes the variable with either the highest variance inflation factor (VIF), or the weakest, least significant or least informative bivariate (individual) relationship with the response variable, according to a given criterion.

Usage

```
corSelect(data, sp.cols = NULL, var.cols, coeff = TRUE,
cor.thresh = ifelse(isTRUE(coeff), 0.8, 0.05),
select = ifelse(is.null(sp.cols), "VIF", "p.value"), family = "auto",
use = "pairwise.complete.obs", method = "pearson", verbosity = 1)
```

Arguments

data	a data frame containing the response and predictor variables.
sp.cols	name or index number of the column of 'data' that contains the response (e.g. species) variable. Currently, only one 'sp.cols' can be used at a time, so an error message is returned if length(sp.cols) > 1. If left NULL, 'select' will be "VIF" by default.
var.cols	names or index numbers of the columns of 'data' that contain the predictor variables.

coeff   logical value indicating whether two variables should be considered highly cor-
                       related based on the magnitude of their coefficient of correlation. The default
                       is TRUE. If set to FALSE, this classification will be based on the p-value of
                       the correlation, but mind that (with sufficient sample size) correlations can be
                       statistically significant even if weak.

cor.thresh   if coeff=TRUE (the default): threshold value of correlation coefficient above
                       which (or below which, for negative correlations) two predictor variables are
                       considered highly correlated. The default is 0.8. If coeff=FALSE: threshold
                       value of p-value below which two predictor variables are considered highly (or
                       significantly) correlated. The default is 0.05.

select   character value indicating the criterion for excluding variables among those that
                       are highly correlated. Can be "VIF" (the default if 'sp.cols' is NULL), "p.value"
                       (the default if 'sp.cols' is specified), "AIC", "BIC", or "cor" (see Details).

family   If 'sp.col' is not NULL, the error distribution and (optionally) the link function
                       to use for assessing significant / informative variables (see [glm](#) or [family](#) for
                       details). The default "auto" automatically uses "binomial" family for response
                       variables containing only values of 0 and 1; "poisson" for positive integer re-
                       sponses (i.e. count data); "Gamma" for positive non-integer; and "gaussian"
                       (i.e., linear models) otherwise.

use   argument to pass to [cor](#) indicating what to do when there are missing val-
                       ues. Can be "pairwise.complete.obs" (the default here), "everything", "all.obs",
                       "complete.obs", "na.or.complete".

method   argument to pass to [cor](#) specifying the correlation coefficient to use. Can be
                       "pearson" (the default), "kendall" or "spearman".

verbosity   integer value indicating the amount of messages to display. The default is 1, for
                       a medium amount of messages. Use 2 for more messages.

Details

Correlations among variables are often considered problematic in multivariate models, as they in-
flate the variance of coefficients and thus may bias the interpretation of the effects of those variables
on the response (Legendre & Legendre 2012). Note, however, that the perceived problem often
stems from misconceptions about the interpretation of multiple regression models, and that re-
moving (albeit correlated) variables usually reduces predictive power (Morrissey & Ruxton 2018,
Gregorich et al. 2021, Vanhove 2021). Removing high correlations is, however, a way of reducing
the number of variables to include in a model, when the potentially meaningful variables are still
numerous and no better a priori selection criterion is available.

One of the strategies to reduce correlations within a dataset consists of excluding one from each pair
of highly correlated variables. However, it is not always straightforward (or ecological knowledge
is not alway sufficient) to choose which variable to exclude. This function selects among correlated
variables based either on their variance inflation factor (VIF: Marquardt 1970; Mansfield & Helms
1982) within the variables dataset (obtained with the [multicol](#) function and recalculated iteratively
after each variable exclusion); or on their relationship with the response, by simply computing the
[cor](#)relation between each variable and the response and excluding the variable with the smallest
absolute coefficient; or by building a bivariate generalized linear model ([glm](#)) of each variable
against the response and excluding, among each of two correlated variables, the one with the largest
(worst) p-value, AIC (Akaike's Information Criterion: Akaike, 1973) or BIC (Bayesian Information

Criterion, also known as Schwarz criterion, SBC or SBIC: Schwarz, 1978), which is calculated with the FDR function.

If 'select' is NULL, or if 'select' is other than "VIF" but 'sp.cols' is NULL, the function returns only a table showing the pairs of variables that are correlated beyond the given threshold, without selection or exclusion. If the 'select' criterion requires assessing bivariate relationships and 'sp.cols' is provided, the function uses only the rows of the dataset where 'sp.cols' (used as the response variable) contains finite values against which the predictor variables can be modelled; rows with NA or NaN in 'sp.cols' are thus excluded from the calculation of correlations among predictor variables.

Value

This function returns a list of 7 elements (unless select=NULL, in which case it returns only the first of these elements):

high.correlations

> data frame showing the pairs of input variables that are correlated beyond the given threshold, their correlation coefficient and its associated p-value.

bivariate.significance

> data frame with the individual p-value, AIC, BIC and correlation coefficient (if one of these was the 'select' criterion and if 'sp.cols' was provided) of each of the highly correlated variables against the response variable.

excluded.vars   character vector containing the names of the variables to exclude (i.e., from each highly correlated pair, the variable with the worse 'select' score.

selected.vars   character vector containing the names of the variables to select (i.e., the non-correlated variables and, from each correlated pair, the variable with the better 'select' score).

selected.var.cols

> integer vector containing the column indices of the selected variables in 'data'.

strongest.remaining.corr

> numerical value indicating the strongest correlation coefficient among the selected variables.

remaining.multicollinearity

> data frame showing the multicollinearity among the selected variables.

distPres   *(Inverse) distance to the nearest presence*

Description

This function takes a matrix or data frame containing species presence (1) and absence (0) data and their spatial coordinates (optionally also a pre-calculated distance matrix between all localities), and calculates the (inverse) distance from each locality to the nearest presence locality for each species.

Usage

```
distPres(data, sp.cols, coord.cols = NULL, id.col = NULL,
dist.mat = NULL, method = "euclidian", suffix = "_D", p = 1,
inv = TRUE)
```

Arguments

data	a matrix or data frame containing, at least, two columns with spatial coordinates, and one column per species containing their presence (1) and absence (0) data, with localities in rows.
sp.cols	names or index numbers of the columns containing the species presences and absences in data. It must contain only zeros (0) for absences and ones (1) for presences.
coord.cols	names or index numbers of the columns containing the spatial coordinates in data (in this order, x and y, or longitude and latitude).
id.col	optionally, the name or index number of a column (to be included in the output) containing locality identifiers in data.
dist.mat	optionally, if you do not want distances calculated with any of the methods available in [dist](), you may provide a distance matrix calculated elsewhere for the localities in data.
method	the method with which to calculate distances between localities. Available options are those of [dist](). The default is "euclidian".
suffix	character indicating the suffix to add to the distance columns in the resulting data frame. The default is "_D".
p	the power to which distance should be raised. The default is 1; use 2 or higher if you want more conservative distances.
inv	logical value indicating whether distance should be inverted, i.e. standardized to vary between 0 and 1 and then subtracted from 1, so that it varies between 0 and 1 and higher values mean closer to presence. The default is TRUE, which is adequate as a fuzzy version of presence-absence (for using e.g. with [fuzSim]() and [simMat]()). In this case, presences maintain the value 1, and inverse distance to presence is calculated only for absence localities.

Details

This function can be used to calculate a simple spatial interpolation model of a species' distribution (e.g. Barbosa 2015, Areias-Guerreiro et al. 2016).

Value

This function returns a matrix or data frame containing the identifier column (if provided in 'id.col') and one column per species containing the distance (inverse by default) from each locality to the nearest presence of that species.

entropy   *(Fuzzy) entropy*

Description

This function computes fuzzy entropy (Kosko 1986, Estrada & Real 2021), or optionally Shannon's (1948) entropy.

Usage

```
entropy(data, sp.cols = 1:ncol(data), method = "fuzzy", base = exp(1),
plot = TRUE, plot.type = "lollipop", na.rm = TRUE, ...)
```

Arguments

`data`	a vector, matrix or data frame containing the data to analyse.
`sp.cols`	names or index numbers of the columns of 'data' that contain the values for which to compute entropy (if 'data' is not a vector). The default is to use all columns.
`method`	character value indicating the method to use. Can be "fuzzy" (the default) or "Shannon". The former requires the input to be a fuzzy system (e.g. Favourability values), while the latter requires probabilities. If method="Shannon" and the values for a vector or column do not sum up to 1, they are divided by their sum so that this additional requirement is met (Estrada & Real 2021).
`base`	base for computing the logarithm if method="Shannon". The default is the natural logarithm.
`plot`	logical value indicating whether to plot the results (if 'data' has more than one column). The default is TRUE.
`plot.type`	character value indicating the type of plot to produce (if plot=TRUE). Can be "lollipop" (the default) or "barplot".
`na.rm`	logical value indicating whether NA values should be removed before computations. The default is TRUE.
`...`	additional arguments to be passed to `barplot` or to `modEvA::lollipop`.

Details

Fuzzy entropy (Kosko 1986) applies to fuzzy systems (such as Favourability) and it can take values between zero and one. Fuzzy entropy equals one when the distribution of the values is uniform, i.e. 0.5 in all localities. The smaller the entropy, the more orderly the distribution of the values, i.e. the closer they are to 0 or 1, distinguishing (potential) presences and absences more clearly. Fuzzy entropy can reflect the overall degree of uncertainty in a species' distribution model predictions, and it is directly comparable across species and study areas (Estrada & Real 2021).

Shannon's entropy requires that the input values are probabilities and sum up to 1 (Shannon 1948). This makes sense when analysing the probability that a unique event occurs in a finite universe. However, if a species has more than one presence, the sum of probabilities in all localities equals the number of presences. To satisfy the condition that the inputs sum up to 1, this function divides each value by the sum of values when this is not the case (if method="Shannon"). Notice that this has a mathematical justification but not a biogeographical sense, and (unlike fuzzy entropy) the results are comparable only between models based on the same number of presences + absences, e.g. in a context of selection of variables for a model (Estrada & Real 2021).

Value

This function returns a numeric value of entropy for 'data' (if it is a numeric vector) or for each of 'sp.cols' in 'data' (if it is a matrix or data frame). Optionally (and by default), a plot is also produced with these values (if there is more than one column) for visual comparison.

Fav   *Favourability (probability without the effect of sample prevalence)*

Description

Computes prevalence-independent favourability for a species' presence, based on a presence/(pseudo)absence model object, or on a vector of predicted probability values plus either the modelled binary response variable, the total number of modelled ones and zeros, or the prevalence (proportion of ones) in the modelled binary response (i.e., in the training data).

Usage

```
Fav(model = NULL, obs = NULL, pred = NULL, n1n0 = NULL, sample.preval = NULL,
method = "RBV", true.preval = NULL, verbosity = 2)
```

Arguments

model   a binary-response, presence/(pseudo)absence probability-producing model object of class "glm", "gam", "gbm", "randomForest" or "bart" (computed with keeptrees=TRUE), obtained with weights=NULL.

obs   alternatively to 'model', a vector of the 1 and 0 values of the binary response variable (e.g. presence-absence of a species) in the model training data. This argument is ignored if 'model' is provided.

pred   alternatively to 'model', a numeric vector, RasterLayer or SpatRaster of predicted presence probability values, produced by a presence/(pseudo)absence modelling method yielding presence probability (obtained with weights=NULL). This argument is ignored if 'model' is provided.

n1n0	alternatively to 'obs' or 'sample.preval', an integer vector of length 2 providing the total numbers of modelled ones and zeros (in this order) of the binary response variable in the model training data. Ignored if 'obs' or 'model' is provided.
sample.preval	alternatively to 'obs' or 'n1n0', the prevalence (proportion of ones) of the binary response variable in the model training data. Ignored if 'model' is provided.
method	either "RBV" for the original Real, Barbosa & Vargas (2006) procedure, or "AT" if you want to try out the modification proposed by Albert & Thuiller (2008) (but see Details!).
true.preval	the true prevalence (as opposed to sample prevalence), necessary if you want to try the "AT" method (but see Details!).
verbosity	numeric value indicating the amount of messages to display; currently meaningful values are 0, 1, and 2 (the default).

Details

Methods such as Generalized Linear Models, Generalized Additive Models, Random Forests, Boosted Regression Trees / Generalized Boosted Models, Bayesian Additive Regression Trees and several others, are widely used for modelling species' potential distributions using presence/absence data and a set of predictor variables. These models predict presence probability, which (unless presences and abences are given different weights) incorporates the prevalence (proportion of presences) of the species in the modelled sample. So, predictions for restricted species are always generally low, while predictions for widespread species are always generally higher, regardless of the actual environmental quality. Barbosa (2006) and Real, Barbosa & Vargas (2006) proposed an environmental favourability function which is based on presence probability and cancels out uneven proportions of presences and absences in the modelled data. Favourability thus assesses the extent to which the environmental conditions change the probability of occurrence of a species with respect to its overall prevalence in the study area. Model predictions become, therefore, directly comparable among species with different prevalences, without the need to artificially assign different weights to presences and absences.

Using simulated data, Albert & Thuiller (2008) proposed a modification to the favourability function, but it requires knowing the true prevalence of the species (not just the prevalence in the modelled sample), which is rarely possible in real-world modelling. Besides, this suggestion was based on the misunderstanding that the favourability function was a way to obtain the probability of occurrence when prevalence differs from 50%, which is incorrect (see Acevedo & Real 2012).

To get environmental favourability with either the Real, Barbosa & Vargas ("RBV") or the Albert & Thuiller ("AT") method, you just need to get model predictions of presence probability from your data, together with the proportions of presences and absences in the modelled sample, and then use the 'Fav' function. Input data for this function are either a model object of an implemented class, or the vector of presences-absences (1-0) of your species and the corresponding presence probability values, obtained e.g. with predict(mymodel, mydata, type = "response"). Alternatively to the presences-absences, you can provide either the sample prevalence or the numbers of presences and absences in the dataset that was used to generate the presence probabilities. In case you want to use the "AT" method (but see Acevedo & Real 2012), you also need to provide the true (besides the sample) prevalence of your species.

Value

If 'model' is provided or if 'pred' is a numeric vector, the function returns a numeric vector of the favourability values. If 'model' is not provided (which would override other arguments) and 'pred' is a RasterLayer or a SpatRaster, the function returns an object of the same class, containing the favourability values.

Note

This function is applicable only to presence probability values obtained without weighting presences and absences differently (i.e. with weights=NULL), thus reflecting the sample prevalence, which is generally the default in presence/absence modelling functions (like `glm`). Note, however, that some modelling packages may use different defaults when calling these functions, e.g. biomod2::BIOMOD_Modeling() with automatically generated pseudo-absences.

---

favClass   *Classify favourability into 3 categories (low, intermediate, high)*

Description

This function takes a vector of [Fav](#)ourability values and reclassifies them into 3 increasing categories: low, intermediate or high. By default, the breaks between these classes are 0.2 and 0.8 (see Details), although these can be changed by the user.

Usage

```
favClass(fav, breaks = c(0.2, 0.8), character = FALSE)
```

Arguments

fav	a numeric vector of favourability values (obtained, e.g., with functions [Fav](#) or [multGLM](#)).
breaks	a numeric vector of length 2 containing the two values which will divide fav into the 3 classes. Defaults to c(0.2, 0.8) following the literature (see Details).
character	logical value indicating whether the result should be returned in character rather numeric form. Defaults to FALSE.

Details

Some applications of species distribution models imply setting a threshold to separate areas with high and low probability or favourability for occurrence (see, e.g., [bioThreat](#)). However, it makes little sense to establish as markedly different areas with, for example, 0.49 and 0.51 favourability values (Hosmer & Lemeshow, 1989). It may thus be wiser to open a gap between values considered as clearly favourable and clearly unfavourable. When this option is taken in the literature, commonly used breaks are 0.8 as a threshold to classify highly favourable values, as the odds are more than 4:1 favourable to the species; 0.2 as a threshold below which to consider highly unfavourable values, as odds are less than 1:4; and classifying the remaining values as intermediate favourability (e.g., Munoz & Real 2006, Olivero et al. 2016).

Value

This function returns either an integer or a character vector (following the 'character' argument, which is set to FALSE by default), of the same length as fav, reclassifying it into 3 categories: 1 ('low'), 2 ('intermediate'), or 3 ('high').

data.frame(fav = fav, favcl_num = favClass(fav),
favcl_chr = favClass(fav, character = TRUE))
```

FDR   *False Discovery Rate*

Description

Calculate the false discovery rate (type I error) under repeated testing and determine which variables to select and to exclude from multivariate analysis.

Usage

```
FDR(data = NULL, sp.cols = NULL, var.cols = NULL, pvalues = NULL,
model.type = NULL, family = "auto", correction = "fdr", q = 0.05,
verbose = NULL, verbosity = 1, simplif = FALSE)
```

Arguments

data	a data frame containing the response and predictor variables (one in each column).
sp.cols	name or index number of the column containing the response variable (currently implemented for only one response variable at a time).
var.cols	names or index numbers of the columns containing the predictor variables.

pvalues	optionally, instead of 'data', 'sp.cols' and 'var.cols', a data frame with the names of the predictor variables in the first column and their bivariate p-values (obtained elsewhere) in the second column. Example: pvalues <- data.frame(var = letters[1:5], pval = c(0.02, 0.004, 0.07, 0.03, 0.05)).
model.type	this argument (previously a character value, either "LM" or "GLM") is now deprecated and ignored with a warning if provided. This information is now included in argument 'family' – e.g., if you want linear models (LM), you can set 'family = "gaussian"'.
family	The error distribution and (optionally) the link function to use (see glm or family for details). The default "auto" automatically uses "binomial" family for response variables containing only values of 0 and 1; "poisson" for positive integer responses (i.e. count data); "Gamma" for positive non-integer; and "gaussian" (i.e., linear models) otherwise.
correction	the correction procedure to apply to the p-values; see p.adjust.methods for available options and p.adjust for more information. The default is "fdr".
q	the threshold value of FDR-corrected significance above which to reject variables. Defaults to 0.05.
verbose	deprecated argument, replaced by 'verbosity' (below).
verbosity	integer value indicating the amount of messages to display. The default is 1, for a medium amount of messages. Use 2 for more messages.
simplif	logical value indicating if simplified results should be provided (see Value).

Details

It is common in ecology to search for statistical relationships between species' occurrence and a set of predictor variables. However, when a large number of variables is analysed (compared to the number of observations), false findings may arise due to repeated testing. Garcia (2003) recommended controlling the false discovery rate (FDR; Benjamini & Hochberg 1995) in ecological studies. The p.adjust R function performs this and other corrections to the significance (p) values of variables under repeated testing. The 'FDR' function performs repeated regressions (either linear or logistic) or uses already-obtained p values for a set of variables; calculates the FDR with 'p.adjust'; and shows which variables should be retained for or excluded from further multivariate analysis according to their corrected p values (see, for example, Barbosa, Real & Vargas 2009).

The FDR function uses the Benjamini & Hochberg ("BH", alias "fdr") correction by default, but check the p.adjust documentation for other available methods, namely "BY", which allows for non-independent data. Input data may be the response variable (for example, the presence-absence or abundance of a species) and the predictors (a table with one independent variable in each column, with the same number of rows and in the same order as the response); there should be no missing values in the data. Alternatively, you may already have performed the univariate regressions and have a set of variables and corresponding p values which you want to correct with FDR; in this case, get a table with your variables' names in the first column and their p values in the second column, and supply it as the 'pvalues' argument (no need to provide response or predictors in this case).

Value

If simplif = TRUE, this function returns a data frame with the variables' names as row names and 4 columns containing, respectively, their individual (bivariate) coefficients against the response,

their individual AIC (Akaike's Information Criterion; Akaike, 1973), BIC (Bayesian Information Criterion, also known as Schwarz criterion, SBC, SBIC; Schwarz, 1978), p-value and adjusted p-value according to the applied 'correction'. If simplif = FALSE (the default), the result is a list of two such data frames:

exclude   with the variables to exclude.

select   with the variables to select (under the given 'q' value).

---

fuzSim   *Fuzzy similarity*

Description

This function calculates fuzzy similarity, based on a fuzzy version of the binary similarity index specified in method, between two binary (0 or 1) or fuzzy (between 0 and 1) variables.

Usage

```
fuzSim(x, y, method, na.rm = TRUE)
```

Arguments

x   a vector of (optionally fuzzy) presence-absence data, with 1 meaning presence, 0 meaning absence, and values in between meaning fuzzy presence (or the degree to which each locality belongs to the set of species presences, or to which each species belongs to the locality; Zadeh, 1965). Fuzzy presence-absence can be obtained, for example, with functions [multGLM](), [multTSA]() or [distPres]() in this package.

y   a vector similar to 'x', of the same length and in the same order.

method   the similarity index to compute between x and y. Currently available options are "Jaccard", "Sorensen", "Simpson" and "Baroni" (see Details).

na.rm   logical value indicating whether NA values should be ignored. The default is TRUE.

Details

Similarity between ecological communities, beta diversity patterns, biotic regions, and distributional relationships among species are commonly determined based on pair-wise (dis)similarities in species' occurrence patterns. Some of the most commonly employed similarity indices are those of Jaccard (1901), Sorensen (1948), Simpson (1960) and Baroni-Urbani & Buser (1976), which are here implemented in their fuzzy versions (Barbosa, 2015), able to deal with both binary and fuzzy data. Jaccard's and Baroni's indices have associated tables of significant values (Baroni-Urbani & Buser 1976, Real & Vargas 1996, Real 1999).

Jaccard's and Sorensen's indices have also been recommended as prevalence-independent metrics for evaluating the performance of models of species distributions and ecological niches (Leroy et al. 2018). These indices are equivalent to other previously recommended model evaluation metrics: the F-measure (which equals Sorensen's index), and the proxy of the F-measure for presence-background data, which equals 2 times Jaccard's index (Li and Guo 2013, Leroy et al. 2018).

Value

The function returns a value between 0 and 1 representing the fuzzy similarity between the provided 'x' and 'y' vectors. Note, for example, that Jaccard similarity can be converted to dissimilarity (or Jaccard distance) if subtracted from 1, while 1-Sorensen is not a proper distance metric as it lacks

the property of triangle inequality (see https://en.wikipedia.org/wiki/S%C3%B8rensen%E2%80%93Dice_coefficient).

Note

The formulas used in this function may look slighty different from some of their published versions (e.g. Baroni-Urbani & Buser 1976), not only because the letters are switched, but because here the A and B are the numbers of attributes present in each element, whether or not they are also present in the other one. Thus, our 'A+B' is equivalent to 'A+B+C' in formulas where A and B are the numbers of attributes present in one but not the other element, and our A+B-C is equivalent to their A+B+C. The formulas used here (adapted from Olivero et al. 1998) are faster to calculate, visibly for large datasets.

fuzSim(fav[, "Abrigh_F"], fav[, "Afissa_F"], method = "Baroni")
```

---

fuzzyConsensus *Fuzzy consensus among model predictions*

Description

This function takes a data frame or a (multilayer) SpatRaster map of favourability predictions (i.e., directly comparable predictions obtained from presence probability; see Fav) and it computes the consensus favourability, i.e., a row-wise weighted mean in which larger weights are assigned to models with higher loadings in the first axis of a principal components analysis (Baquero et al. 2021).

Usage

```
fuzzyConsensus(data, weights = "PCA1", simplif = TRUE, plot = TRUE,
biplot = FALSE, verbosity = 2, do.par = TRUE)
```

Arguments

data	matrix, data frame or (multilayer) 'SpatRaster' map containing the favourability values to combine.
weights	method for computing the weights for the weighted average of favourability values. Currently only "PCA1" is implemented.

simplif	logical value. If TRUE (the default), the output includes only the numeric vector of weighted mean favourability. If set to FALSE, the output will include also the complete PCA result (if weights="PCA1").
plot	logical value indicating whether to produce a barplot of the PCA axis loadings. The default is TRUE.
biplot	logical value indicating whether to produce a [biplot] of the PCA. The default is FALSE, as it makes computation slower.
verbosity	integer value indicating the amount of messages to display in the console. The default is to emit all messages available.
do.par	logical value indicating whether to override the current plotting parameters (restoring them on exit). The default is TRUE.

Details

Species distribution models are often computed using different modelling methods and/or climate scenarios. One way to summarize or combine them is to do a principal components analysis (PCA) of the different model predictions: The first axis of this PCA captures consistent spatial patterns in the predicted values across the different models (Araujo, Pearson, et al. 2005; Araujo, Whittaker, et al. 2005; Marmion et al. 2009; Thuiller 2004). However, the units of the PCA axes are difficult to interpret. Baquero et al. (2021) solved this by computing a weighted average of the favourability values (which are commensurable and therefore directly comparable across species and study areas; Real et al. 2006, Acevedo & Real 2012), using the loadings of the first PCA axis as weights. The result is therefore in the same scale as favourability, and it incorporates the degree of consensus among models, which dictates how much weight each model has in the prediction, thus avoiding disparate predictions to be blindly mixed and averaged out (Baquero et al. 2021).

Value

If simplif=TRUE (the default), the function returns a numeric vector with length equal to the number of rows in 'data' (if 'data' is a matrix or data frame), or a 'SpatRaster' layer (if 'data' is a 'SpatRaster' object), with the consensus among the input favourabilities. If simplif=FALSE, the function returns a list containing, additionally, the output of [prcomp].

## End(Not run)
```

---

fuzzyOverlay	*Row-wise overlay operations based on fuzzy logic*

Description

Logical and set operations are useful for comparative distribution modelling, to assess consensus or mismatches between the predictions of different models, and to quantify differences between models obtained for different time periods. Fuzzy set theory (Zadeh 1965, Barbosa & Real 2012) allows performing such operations without converting model predictions from continuous to binary, thus avoiding the application of arbitrary thresholds and the distortion or over-simplification of those predictions. The result is a continuous numerical value quantifying the intersection, union, sum, or other operation among model predictions, whether binary or continuous.

Usage

```
fuzzyOverlay(data, overlay.cols = 1:ncol(data), op = "intersection",
na.rm = FALSE, round.digits = 2)
```

Arguments

data	matrix or data frame containing the model predictions to compare.
overlay.cols	vector of the names or index numbers of the columns to compare. The default is all columns in data.
op	character value indicating the operation to perform between the prediction columns in 'data'. Can be "consensus" for the arithmetic mean of predictions (or the fuzzy equivalent of the proportion of models that agree that the species occurs at each site), "fuzzy_and" or "intersection" for fuzzy intersection; "fuzzy_or" or "union" for fuzzy union; "prob_and" or "prob_or" for probabilistic and/or, respectively (see Details); "maintenance" for the values where all predictions for the same row (rounded to the number of digits specified in the next argument) are the same. If 'data' has only two columns to compare, you can also calculate"xor" for exclusive 'or', "AnotB"" for the the occurrence of the species in column 1 in detriment of that in column 2, "expansion" for the prediction increase in rows where column 2 has higher values than column 1, "contraction" for the prediction decrease in rows where column 2 has lower values than column 1, or "change" for a mix of the latter two, with positive values where there has been an increase and negative values where there was decrease in favourability from columns 1 to 2. For expansion, contraction and maintenance, rows where the values do not satisfy the condition (i.e. second column larger, smaller, or roughly equal to the first column) get a value of zero.
na.rm	logical value indicating if NA values should be ignored. The default is FALSE, so rows with NA in any of the prediction columns get NA as a result.
round.digits	integer value indicating the number of decimal places to be used if op = "maintenance". The default is 2.

Details

If your predictions are probabilities, "prob_and" (probabilistic 'and') gives the probability of all species in 'data' occurring simultaneously by multiplying all probabilities; and "prob_or" (probabilistic 'or') gives the probability of any of them occurring at each site. These can be quite restrictive, though; probabilistic "and" can give particularly irrealistically small values.

If you have (or convert your probabilities to) favourability predictions, which can be used directly with fuzzy logic (Real et al. 2006; see [Fav](#) function), you can use "fuzzy_and" or "intersection" to get the favourability for all species co-occurring at each site, and "fuzzy_or" or "union" to get favourability for any of them to occur at each site (Barbosa & Real 2012).

Value

This function returns a vector, with length equal to the number of rows in data, containing the row-wise result of the operation performed.

"Abrigh_imag"), op = "change")

preds$Abrigh_maint <- fuzzyOverlay(preds, overlay.cols = c("Abrigh_F",
"Abrigh_imag"), op = "maintenance")

head(preds)
```

---

fuzzyRangeChange   *Range change based on continuous (fuzzy) values*

Description

This function quantifies overall range change (expansion, contraction, maintenance and balance) based on either presence-absence data or the continuous predictions of two models.

Usage

```
fuzzyRangeChange(pred1, pred2, number = TRUE, prop = TRUE,
na.rm = TRUE, round.digits = 2,
measures = c("Gain", "Loss", "Stable positive", "Stable negative", "Balance"),
plot = TRUE, plot.type = "lollipop", x.lab = TRUE, ...)
```

Arguments

pred1   numeric vector containing the predictions (between 0 and 1) of the model that
                 will serve as reference.

pred2	numeric vector containing the predictions (between 0 and 1) of the model whose change will be calculated. Must be of the same length and in the same order as 'pred1'.
number	logical value indicating if results should include the fuzzy number of cases. The default is TRUE.
prop	logical value indicating if results should include the proportion of the total number of cases. The default is TRUE.
na.rm	logical value indicating whether NA values should be ignored. The default is TRUE.
round.digits	argument to pass to [fuzzyOverlay](#), indicating the number of decimal places to which to round 'pred' for calculating 'maintenance' or 'stability'. The default is 2.
measures	character vector listing the range change measures to calculate. The default includes all available measures.
plot	logical value indicating whether to plot the results. The default is TRUE.
plot.type	character value indicating the type of plot to produce (if plot=TRUE). Can be "lollipop" (the default) or "barplot".
x.lab	logical value indicating whether to add the x axis labels to the plot (i.e., the names below each lollipop or bar). The default is TRUE, but users may set it to FALSE and then add labels differently (e.g. with different names or rotations).
...	additional arguments to pass to barplot or to modEvA::lollipop (if plot=TRUE).

Value

This function returns a data frame with the following values in different rows (among those included in 'measures'):

Gain	sum of the predicted values that have increased from 'pred1' to 'pred2' (fuzzy equivalent of the number of localities that gained presence)
Loss	sum of the predicted values that have decreased from 'pred1' to 'pred2' (fuzzy equivalent of the number of localities that lost presence)
Stable positive	
	fuzzy equivalent of the number of (predicted) presences that have remained as such (when rounded to 'round.digits') between 'pred1' and 'pred2'
Stable negative	
	fuzzy equivalent of the number of (predicted) absences that have remained as such (when rounded to 'round.digits') between 'pred1' and 'pred2')
Balance	sum of the change in predicted values from 'pred1' to 'pred2' (fuzzy equivalent of the balance of gained and lost presences)

If number=TRUE (the default), there is a column named "Number" with the number of localities in each of the above categories. If prop=TRUE (the default), there is a column named "Proportion" in which this number is divided by the total number of reference values (i.e., the fuzzy range or fuzzy non-range size). If plot=TRUE (the default), a plot is also produced representing the last column of the result data frame.

fuzzyRangeChange(fav_current, fav_imag, plot.type = "barplot")
```

---

getPreds *Get model predictions*

Description

This function allows getting the predictions of multiple models when applied to a given dataset. It can be useful if you have a list of model objects (e.g. resulting from [multGLM]()) and want to apply them to a new data set containing the same variables for another region or time period. There are options to include the logit link ('Y') and/or 'Favourability' (see [Fav]()).

Usage

```
getPreds(data, models, id.col = NULL, Y = FALSE, P = TRUE,
Favourability = TRUE, incl.input = FALSE, verbosity = 2)
```

Arguments

data	an object of class either 'data.frame' or 'RasterStack' to which to apply the 'models' (below) to get their predictions; must contain all variables (with the same names, case-sensitive) included in any of the 'models'.
models	an object of class 'list' containing one or more model objects, obtained e.g. with function [glm](#) or [multGLM](#).
id.col	optionally, the index number of a column of 'data' containing row identifiers, to be included in the result. Ignored if incl.input = TRUE, or if 'data' is a RasterStack rather than a data frame.
Y	logical, whether to include the logit link (y) value in the predictions.
P	logical, whether to include the probability value in the predictions.
Favourability	logical, whether to include Favourability in the predictions (see [Fav](#)).
incl.input	logical, whether to include input columns in the output data frame (if the 'data' input is a data frame too). The default is FALSE.
verbosity	numeric value indicating the amount of messages to display; currently meaningful values are 0, 1, and 2 (the default).

Value

This function returns the model predictions in an object of the same class as the input 'data', i.e. either a data frame or a RasterStack.

Favourability = TRUE)

head(preds)
```

---

gridRecords   *Grid (or thin) point occurrence records to the resolution of a raster map*

Description

This function takes a (single or multi-layer) SpatRaster or a Raster* object and a set of spatial coordinates of a species' presence (and optionally absence) records, and returns a data frame of the presences and absences with their raster values in the grid of pixels (cells). This is analogous to removing duplicates and thinning points (both presences and absences) with a distance equal to the pixel size of the raster map(s) on which analysis will be based.

Usage

```
gridRecords(rst, pres.coords, abs.coords = NULL, absences = TRUE,
species = NULL, na.rm = TRUE, plot = FALSE)
```

Arguments

rst   a Raster* or SpatRaster object (the latter is processed faster) with the desired
                    spatial resolution and extent for the species presence-(pseudo)absence data, and
                    the layer(s) whose values to extract for those data.

pres.coords	a SpatVector of points, or an object inheriting class 'data.frame' with 2 columns containing, respectively, the x and y, or longitude and latitude coordinates (in this order, and in the same coordinate reference system as 'rst') of the points where species presence was recorded.
abs.coords	(optional) same as 'pres.coords' but for points where the species was not recorded. If abs.coords=NULL and absences=TRUE (the default), all pixels that are not intersected by 'pres.coords' will be returned as having absence of records.
absences	logical value indicating whether pixels without presence records should be returned as absences. The default is TRUE.
species	(optional) character vector, of the same length as 'nrow(pres.coords)', indicating the species to which each pair of coordinates corresponds. Useful for gridding records of more than one species at a time. Its unique values will be used as column names in the output. If this argument is specified, 'abs.coords' cannot be used.
na.rm	logical value indicating whether pixels with NA in all of the 'rst' layers should be excluded from the output data frame. The default is TRUE.
plot	logical value specifying whether to plot the resulting presences and absences. The default is FALSE (for back-compatibility).

Details

See e.g. Baez et al. (2020), where this function was first used to get unique presences and absences from point occurrence data at the spatial resolution of marine raster variables.

You should consider cleaning the coordinates beforehand, e.g. with cleanCoords.

If your output has an overly large and/or spatially biased set of absences, you can use selectAbsences afterwards.

Value

This function returns a data frame with the following columns:

'presence'	integer, 1 for the cells (pixels) with at least one presence point; and (if absences=TRUE) 0 for the cells without any presence point, or with at least one absence point (if 'abs.coords' are provided) AND no presence points. If the 'species' argument is provided, instead of 'presence' you get one column named as each species.
'x', 'y'	centroid coordinates of each cell (pixel).
'cell'	the pixel identifier in 'rst'.
one column for each layer in 'rst'	value of each pixel for each layer.

If plot=TRUE, the fuction also plots the resulting presences (blue "plus" signs) and absences (red "minus" signs).

Note

This function requires either the **raster** or the **terra** package, depending on the class of 'rst'.

integerCols	*Classify integer columns*

Description

This function detects which numeric columns in a data frame contain only whole numbers, and converts those columns to integer class, so that they take up less space.

Usage

```
integerCols(data)
```

Arguments

data   a data frame containing possibly integer columns classified as "numeric".

Value

The function returns a data frame with the same columns as 'data', but with those that are numeric and contain only whole numbers (possibly including NA) now classified as "integer".

Author(s)

A. Marcia Barbosa

See Also

[is.integer](), [as.integer](), [multConvert]()

Examples

```
dat <- data.frame(
  var1 = 1:10,
  var2 = as.numeric(1:10),
  var3 = as.numeric(c(1:4, NA, 6:10)),
  var4 = as.numeric(c(1:3, NaN, 5, Inf, 7, -Inf, 9:10)),
  var5 = as.character(1:10),
  var6 = seq(0.1, 1, by = 0.1),
  var7 = letters[1:10]
)  # creates a sample data frame

dat

str(dat)
# var2 classified as "numeric" but contains only whole numbers
# var3 same as var2 but containing also NA values
# var4 same as var2 but containing also NaN and infinite values
# var5 contains only whole numbers but initially classified as factor

dat <- integerCols(dat)

str(dat)
# var2 and var3 now classified as "integer"
# var4 remains as numeric because contains infinite and NaN
# (not integer) values
# var5 remains as factor
```

---

modelTrim | *Trim off non-significant variables from a model*

Description

This function performs a stepwise removal of non-significant variables from a model, following Crawley (2005, 2007). See [stepwise]() for a newer, more complete function that can be used instead.

Usage

```
modelTrim(model, method = "summary", alpha = 0.05)
```

Arguments

`model`	a model object.
`method`	the method for getting the individual p-values. Can be either "summary" for the p-values of the coefficient estimates, or "anova" for the p-values of the variables themselves (see Details).
`alpha`	the p-value above which a variable is removed.

Details

Stepwise variable selection is a common procedure for simplifying models. It maximizes predictive efficiency in an objective and reproducible way, and is useful when the individual importance of the predictors is not known a priori (Hosmer & Lemeshow, 2000). The [step](#) R function performs such procedure using an information criterion (AIC) to select the variables, but it often leaves variables that are not significant in the model. Such variables can be subsequently removed with a manual stepwise procedure (e.g. Crawley 2005, p. 208; Crawley 2007, p. 442 and 601; Barbosa & Real 2010, 2012; Estrada & Arroyo 2012). The 'modelTrim' function performs such removal automatically until all remaining variables are significant. It can also be applied to a full model (i.e., without previous use of the 'step' function), as it serves as a backward stepwise selection procedure based on the significance of the coefficients (if method = "summary", the default) or on the significance of the variables (if method = "anova", better when there are categorical variables in the model). See [stepwise](#) for a more complete stepwise selection procedure.

Value

The input model object after removal of non-significant variables.

# build a stepwise model of a species' occurrence based on
# some of the variables:

mod <- with(rotif.env, step(glm(Abrigh ~ Area + Altitude + AltitudeRange +
HabitatDiversity + HumanPopulation, family = binomial)))

# examine the model:

summary(mod)  # contains non-significant variables

# use modelTrim to get rid of non-significan effects:

mod <- modelTrim(mod)

summary(mod)  # only significant variables now
```

---

modOverlap   *Overall overlap between model predictions*

Description

This function calculates the degree of overlap between the predictions of two models, using niche
comparison metrics such as Schoener's D, Hellinger distance and Warren's I.

Usage

```
modOverlap(pred1, pred2, na.rm = TRUE)
```

Arguments

pred1	numeric vector of the predictions of a (values between 0 and 1).
pred2	numeric vector of the predictions of another model; must be of the same length and in the same order as 'pred1'.
na.rm	logical value indicating whether NA values should be removed prior to calculation. The default is TRUE.

Details

See Warren et al. (2008).

Value

This function returns a list of 3 metrics:

SchoenerD	Schoener's (1968) D statistic for niche overlap, varying between 0 (no overlap) and 1 (identical niches).
WarrenI	the I index of Warren et al. (2008), based on Hellinger distance (below) but re-formulated to also vary between 0 (no overlap) and 1 (identical niches).
HellingerDist	Hellinger distance (as in van der Vaart 1998, p. 211) between probability distributions, varying between 0 and 2.

fav_imag[fav_imag < 0] <- 0
```

```
fav_imag[fav_imag > 1] <- 1

# calculate niche overlap between current and imaginary future predictions:

modOverlap(fav_current, fav_imag)
```

---

multConvert   *Multiple conversion*

Description

This function can simultaneously convert multiple columns of a matrix or data frame.

Usage

```
multConvert(data, conversion, cols = 1:ncol(data))
```

Arguments

data	A matrix or data frame containing columns that need to be converted
conversion	the conversion to apply, e.g. as.factor or a custom-made function
cols	the columns of 'data' to convert

Details

Sometimes we need to change the data type (class, mode) of a variable in R. There are various possible conversions, performed by functions like as.integer, as.factor or as.character. If we need to perform the same conversion on a number of variables (columns) in a data frame, we can convert them all simultaneously using this function. By default it converts all columns in 'data', but you can specify just some of those. 'multConvert' can also be used to apply other kinds of transformations – for example, if you need to divide some of your columns by 100, just write a function to do this and then use 'multConvert' to apply this function to any group of columns.

Value

The input data with the specified columns converted as specified in 'conversion'.

Author(s)

A. Marcia Barbosa

Examples

```
data(rotif.env)

str(rotif.env)

# convert the first 4 columns to character:
converted.rotif.env <- multConvert(data = rotif.env,
conversion = as.character, cols = 1:4)

str(converted.rotif.env)

names(rotif.env)

# divide some columns by 100:

div100 <- function(x) x / 100

rotif.env.cent <- multConvert(data = rotif.env,
conversion = div100, cols = c(6:10, 12:17))

head(rotif.env.cent)
```

---

multGLM   *GLMs with variable selection for multiple species*

Description

This function performs selection of variables and calculates generalized linear models for a set
of presence/absence records in a data frame, with a range of options for data partition, variable
selection, and output form.

Usage

```
multGLM(data, sp.cols, var.cols, id.col = NULL, block.cols = NULL,
family = "binomial", test.sample = 0, FDR = FALSE, correction = "fdr",
FDR.first = TRUE, corSelect = FALSE, coeff = TRUE,
cor.thresh = ifelse(isTRUE(coeff), 0.8, 0.05), cor.method = "pearson",
step = TRUE, trace = 0, start = "null.model", direction = "both",
select = "AIC", trim = TRUE, Y.prediction = FALSE, P.prediction = TRUE,
Favourability = TRUE, group.preds = TRUE, TSA = FALSE, coord.cols = NULL,
degree = 3, verbosity = 2, test.in = "Rao", test.out = "LRT", p.in = 0.05,
p.out = 0.1, ...)
```

Arguments

data   a data frame in wide format (see [splist2presabs](#)) containing, in separate columns,
                your species' binary (0/1) occurrence data and the predictor variables.

sp.cols	names or index numbers of the columns containing the species data to be modelled.
var.cols	names or index numbers of the columns containing the predictor variables to be used for modelling.
id.col	(optional) name or index number of column containing the row identifiers (if defined, it will be included in the output 'predictions' data frame).
block.cols	[UNDER IMPLEMENTATION] names or index numbers of the columns containing predictor variables to force into the model, even when a selection method is applied to the remaining variables.
family	argument to be passed to the [glm](#) function; currently, only 'binomial' is implemented here.
test.sample	a subset of data to set aside for subsequent model testing. Can be a value between 0 and 1 for a proportion of the data to choose randomly (e.g. 0.2 for 20%); or an integer number for a particular number of cases to choose randomly among the records in 'data'; or a vector of integers for the index numbers of the particular rows to set aside; or "Huberty" for his rule of thumb based on the number of variables (Huberty 1994, Fielding & Bell 1997).
FDR	logical value indicating whether to do a preliminary exclusion of variables based on the false discovery rate (see [FDR](#)). The default is FALSE.
correction	argument to pass to the [FDR](#) function if FDR=TRUE. The default is "fdr", but see [p.adjust](#) for other options.
FDR.first	logical value indicating whether FDR exclusion (if FDR=TRUE) should be applied at the beginning. The default is TRUE. If set to FALSE (and if FDR=TRUE), FDR exclusion will be applied after 'corSelect' below.
corSelect	logical value indicating whether to select among highly correlated variables using [corSelect](#). The default is FALSE.
coeff	logical value to pass to [corSelect](#) (if corSelect=TRUE) indicating whether two variables should be considered highly correlated based on the magnitude of their coefficient (rather than p-value) of correlation. The default is TRUE.
cor.thresh	numerical value indicating the correlation threshold to pass to [corSelect](#) (if corSelect=TRUE).
cor.method	character value to pass to [corSelect](#) (if corSelect=TRUE) specifying the correlation coefficient to use. Can be "pearson" (the default), "kendall" or "spearman".
step	logical, whether to perform a stepwise selection of variables, using either the [step](#) function (if select = "AIC" or "BIC") or the [stepwise](#) function (if select = "p.value").
trace	if positive, information is printed during the stepwise selection (if step=TRUE). Larger values may give more detailed information.
start	character string specifying whether to start with the 'null.model' (so that variable selection starts forward) or with the 'full.model' (so selection starts backward). Used only if step=TRUE.
direction	if step=TRUE, argument to be passed to [step](#) or to [stepwise](#) specifying the direction of variable selection. Can be 'forward', 'backward', or 'both' (the default).

select	character string specifying the criterion for stepwise selection of variables if step=TRUE. Options are the default "AIC" (Akaike's Information Criterion; Akaike, 1973); BIC (Bayesian Information Criterion, also known as Schwarz criterion, SBC or SBIC; Schwarz, 1978); or "p.value" (Murtaugh, 2014). The first two options imply using step as the variable selection function, while the last option calls the stepwise function. If you set select="p.value", we recommend also setting trim=FALSE to avoid mixing different significance criteria.
trim	logical value indicating whether to trim off non-significant variables from the models using modelTrim. This argument is TRUE by default (for back-compatibility), and it can be used whether or not step=TRUE – e.g. Crawley (2005, p. 208) and Crawley (2007, p. 442 and 601) recommend that step (with AIC selection) be followed by significance-based backward elimination).
Y.prediction	logical value indicating whether to include output predictions in the scale of the predictor variables (type = "link" in predict.glm).
P.prediction	logical, whether to include output predictions in the scale of the response variable, i.e. probability (type = "response" in predict.glm).
Favourability	logical, whether to apply the [Fav](Fav)ourability function to remove the effect of prevalence on predicted probability (Real et al. 2006) and include its results in the output.
group.preds	logical, whether to group together predictions of similar type ('Y', 'P' or 'F') in the output 'predictions' table (e.g. if FALSE: sp1_Y, sp1_P, sp1_F, sp2_Y, sp2_P, sp2_F; if TRUE: sp1_Y, , sp2_Y, sp1_P, sp2_P, sp1_F, sp2_F).
TSA	logical, whether to add a trend surface analysis (calculated individually for each species) as a spatial variable in each model (with type="Y" – see multTSA for more details). The default is FALSE. If TRUE, this spatial trend will be treated as any other variable, i.e. also considered by arguments 'FDR', 'corSelect', etc.
coord.cols	argument to pass to multTSA (if TSA=TRUE).
degree	argument to pass to multTSA (if TSA=TRUE).
verbosity	numeric value indicating the amount of messages to display, from less to more verbose; currently meaningful values are 0, 1, and 2 (the default).
test.in	argument to pass to stepwise if select="p.value".
test.out	argument to pass to stepwise if select="p.value".
p.in	argument to pass to stepwise if select="p.value".
p.out	argument to pass to stepwise if select="p.value".
...	(for back-compatibility) additional arguments to be passed to modelTrim (if trim=TRUE).

Details

This function automatically calculates binomial GLMs for one or more species (or other binary variables) in a data frame. The function can optionally perform stepwise variable selection using either stepwise or step (and it does so by default) instead of forcing all variables into the models, starting from either the null model (the default, so selection starts forward) or from the full model (so selection starts backward), and using AIC, BIC or statistical significance as a variable selection

criterion. Instead or subsequently, it can also perform stepwise removal of non-significant variables from the models using the `modelTrim` function.

There is also an optional preliminary selection among highly correlated variables, and/or preliminary selection of variables with a significant bivariate relationship with the response, based on the false discovery rate (`FDR`). Note, however, that some variables can be significant in a multivariate model even if they would not have been selected by FDR.

`Fav`ourability can also be calculated by default, removing the effect of training prevalence from occurrence probability and thus allowing direct comparisons between different models (Real et al. 2006; Acevedo & Real 2012).

By default, all data are used in model training, but you can define an optional 'test.sample' to be reserved for model testing afterwards. You may also want to do a previous check for multicollinearity among variables, e.g. the variance inflation factor (VIF), using `multicol`.

The 'multGLM' function will create a list of the resulting models (each with the name of the corresponding species column) and a data frame with their predictions ('Y', 'P' and/or 'F', all of which are optional). If you plan on representing these predictions in a GIS format based on .dbf tables (e.g. ESRI Shapefile), remember that .dbf only allows up to 10 characters in column names; 'multGLM' predictions will add 2 characters (_Y, _P and/or _F) to each of your species column names, so better use species names/codes with up to 8 characters in the data set that you are modelling. You can create (sub)species name abbreviations with the `spCodes` function.

Value

This function returns a list with the following components:

predictions	a data frame with the model predictions (if either of Y.prediction, P.prediction or Favourability are TRUE).
models	a list of the resulting model objects.
variables	a list of character vectors naming the variables finally included in each model according to the specified selection criteria.

Note

With step=TRUE (the default), an error may occur if there are missing values in some of the variables that are selected (see "Warning" in `step`). If this happens, you can use something like data=na.omit(data[, c(sp.col, var.cols)]).

Thanks are due to Prof. Jose Carlos Guerrero at the University of the Republic (Uruguay), who funded the implementation of the options select="p.value" and FDR.first=FALSE.

| multicol | *Analyse multicollinearity in a dataset, including VIF* |

Description

This function analyses multicollinearity in a set of variables or in a model, including the R-squared, tolerance and variance inflation factor (VIF).

Usage

```
multicol(vars = NULL, model = NULL, reorder = TRUE)
```

Arguments

vars   A matrix or data frame containing the numeric variables for which to calculate multicollinearity. Only the 'independent' (predictor, explanatory, right hand side) variables should be entered, as the result obtained for each variable depends on all the other variables present in the analysed data set.

model   Alternatively to 'vars', a model object of class "glm" to calculate 'multicol' among the included variables.

reorder   logical, whether variables should be output in decreasing order or VIF value rather than in their input order. The default is TRUE.

Details

Testing collinearity among covariates is a recommended step of data exploration before applying a statistical model (Zuur et al. 2010). However, you can also calculate multicollinearity among the variables already included in a model.

The multicol function calculates the degree of multicollinearity in a set of numeric variables, using three closely related measures: R squared (the coefficient of determination of a linear regression of each predictor variable on all other predictor variables, i.e., the amount of variation in each variable that is accounted for by other variables in the dataset); tolerance (1 - R squared), i.e. the amount of variation in each variable that is not included in the remaining variables; and the variance inflation factor: VIF = 1 / (1 - R squared), which, in a linear model with these variables as predictors, reflects the degree to which the variance of an estimated regression coefficient is increased due only to the correlations among covariates (Marquardt 1970; Mansfield & Helms 1982).

Value

The function returns a matrix with one row per analysed variable, the names of the variables as row names, and 3 columns: R-squared, Tolerance and VIF.

multicol(OrchardSprays[ , 1:3])
```

| multTSA | *Trend Surface Analysis for multiple species* |

Description

This function performs trend surface analysis for one or more species at a time. It converts categorical presence-absence (1-0) data into continuous surfaces denoting the spatial trend in species' occurrence patterns.

Usage

```
multTSA(data, sp.cols, coord.cols, id.col = NULL, degree = 3,
step = TRUE, criterion = "AIC", type = "P", Favourability = FALSE,
suffix = "_TS", save.models = FALSE, verbosity = 2, ...)
```

Arguments

data	a matrix or data frame containing, at least, two columns with spatial coordinates, and one column per species containing their presence (1) and absence (0) data, with localities in rows.
sp.cols	names or index numbers of the columns containing the species presences and absences in data. Must contain only zeros (0) for absences and ones (1) for presences.
coord.cols	names or index numbers of the columns containing the spatial coordinates in data (x and y, or longitude and latitude, in this order!).
id.col	optionally, the name or index number of a column (to be included in the output) containing locality identifiers in data.
degree	the degree of the spatial polynomial to use (see Details). The default is 3.
step	logical value indicating whether the regression of presence-absence on the spatial polynomial should do a stepwise inclusion of the polynomial terms (using the [step](#) function with default settings, namely backward AIC selection), rather than forcing all terms into the equation. The default is TRUE.
criterion	character value indicating whether the backward stepwise selection of variables (if step = TRUE) should be made according to "AIC" (the default, using the [step](#) function) or to "significance" (using the [modelTrim](#) function).
type	the type of trend surface to obtain. Can be either "Y" for the raw polynomial equation (i.e. in the scale of the predictors, e.g. if you want to use the spatial trend as a predictor variable in a model), "P" for the logit-transformed probability (e.g. if you want to use the output as a prediction of presence probability based on spatial trend alone), or "F" for spatial favourability, i.e., prevalence-independent probability (see [Fav](#)).
Favourability	deprecated argument; linktype should now be used instead, although (at least for the timebeing) this argument will still be accepted (with Favourability=TRUE internally resulting in type="F") for back-compatibility.
suffix	character indicating the suffix to add to the trend surface columns in the resulting data frame. The default is "_TS".
save.models	logical value indicating whether the models obtained from the regressions should be saved and included in the output. The default is FALSE.
verbosity	integer value indicating the amount of messages to display; currently meaningful values are 0, 1, and 2 (the default).
...	additional arguments to be passed to [modelTrim](#) (if step = TRUE and criterion = "significance").

Details

Trend Surface Analysis is a way to model the spatial structure in species' distributions by regressing occurrence data on the spatial coordinates x and y, for a linear trend, or on polynomial terms of these coordinates (x^2, y^2, x*y, etc.), for curvilinear trends (Legendre & Legendre, 1998; Borcard et al., 2011). Second- and third-degree polynomials are often used. 'multTSA' allows specifying the degree of the spatial polynomial to use. By default, it uses a 3rd-degree polynomial and performs stepwise AIC selection of the polynomial terms to include.

Value

This function returns a matrix or data frame containing the identifier column (if provided in 'id.col') and one column per species containing the value predicted by the trend surface analysis. If save.models = TRUE, the output is a list containing this dataframe plus a list of the model objects.

---

pairwiseRangemaps *Pairwise intersection (and union) of range maps*

Description

This function takes a set of rangemaps and returns a matrix containing the areas of their pairwise intersections; optionally, also their individual areas and/our their areas of pairwise unions.

Usage

```
pairwiseRangemaps(rangemaps, projection = NULL, diag = TRUE, unions = TRUE,
verbosity = 2, Ncpu = 1, nchunks = 1, subchunks = NULL,
filename = "rangemap_matrix.csv")
```

Arguments

rangemaps	a character vector of rangemap filenames, including the extension (e.g. ".shp" or ".gpkg"), and the folder paths if not in the woorking directory.
projection	DEPRECATED argument, previously required by function 'PBSmapping::importShapefile', which is now here replaced with 'terra::vect'. Will be ignored with a message if provided. Mind that area computations are more accurate with unprojected input maps (see ?terra::expanse).
diag	logical, whether to fill the diagonal of the resulting matrix with the area of each rangemap. The default is TRUE, and it is also automatically set to TRUE (as it is necessary) if unions = TRUE.
unions	logical, whether to fill the upper triangle of the resulting matrix with the area of union of each pair of rangemaps. The default is TRUE. It is not as computationally intensive as the intersection, as it is calculated not with spatial but with algebraic operations within the matrix (union = area1 + area2 - intersection).
verbosity	integer number indicating the amount of progress messages to display.
Ncpu	integer indicating the number of CPUs (central processing units) to employ if parallel computing is to be used. The default is 1 CPU, which implies no parallel computing, but you may want to increase this if you have many and/or large rangemaps and your machine has more cores that can be used simultaneously. You can find out the total number of cores in you machine with the [detectCores](#) function of the **[parallel](#)** package; a usually wise option is to use all cores except one (i.e., Ncpu = parallel::detectCores()-1).
nchunks	either an integer indicating the number of chunks of rows in which to divide the results matrix for calculations, or character "decreasing" to indicate that the matrix should be divided into chunks of decreasing number of rows (as intersections are calculated in the lower triangle, rows further down the matrix have an increasing number of intersections to compute). Note, however, that rangemap size, not rangemap number, is the main determinant of computation time. The default is 1 (no division of the matrix) but, if you have many rangemaps, the process can get clogged. With chunks, each set of rows of the matrix is calculated and saved to disk, and the memory is cleaned before the next chunk begins.
subchunks	optional integer vector specifying which chunks to actually calculate. This is useful if a previous, time-consuming run of pairwiseRangemaps was interrupted (e.g. by a power outage) and you want to calculate only the remaining chunks.
filename	optional character vector indicating the name of the file to save the resulting matrix to.

Details

This computation can be intensive and slow, especially if you have many and/or large rangemaps, due to the time needed for pairwise spatial operations between them. You can set nchunks="decreasing"

for the matrix to be calculated in parts and the memory cleaned between one part and the next; and, if your computer has more than one core that you can use, you can increase 'Ncpu' to get parallel computing.

Value

This function returns a square matrix containing, in the lower triangle, the area of the pair-wise intersections among the input 'rangemaps'; in the diagonal (if diag = TRUE or union = TRUE), the area of each rangemap; and in the upper triangle (if union = TRUE), the area of the pair-wise unions among the rangemaps.

Note

This function previously used the **PBSmapping** package to import and intersect the rangemaps and to calculate areas. Now it uses the **terra** package instead. Mind that, after the implementation of spherical geometry, area computations are more accurate with unprojected input maps (see ?terra::expanse). Small differences can thus arise between the results of the previous version and the current version (from **fuzzySim** 4.9.4).

percentTestData   *Percent test data*

Description

Based on the work of Schaafsma & van Vark (1979), Huberty (1994) provided a heuristic ("rule of thumb") for determining an adequate proportion of data to set aside for testing species presence/absence models, based on the number of predictor variables that are used (Fielding & Bell 1997). The 'percentTestData' function calculates this proportion as a percentage.

Usage

```
percentTestData(nvar)
```

Arguments

nvar   the number of variables in the model.

Value

A numeric value of the percentage of data to leave out of the model for further model testing.

Author(s)

A. Marcia Barbosa

multGLM

Examples

```
# say you're building a model with 15 variables:

percentTestData(15)

# the result tells you that 21% is an appropriate percentage of data
# to set aside for testing your model, so train it with 79% of the data
```

---

prevalence	*Prevalence*

Description

Prevalence is the proportion of presences of a species in a dataset, which is required (together with presence probability) for computing [Fav](Fav)ourability.

Usage

```
prevalence(obs, model = NULL, event = 1, na.rm = TRUE)
```

Arguments

obs	a vector or a factor of binary observations (e.g. 1 vs. 0, male vs. female, disease vs. no disease, etc.). This argument is ignored if 'model' is provided.
model	alternatively to 'obs', a binary-response model object of class "glm", "gam", "gbm", "randomForest" or "bart". If this argument is provided, 'obs' will be extracted with mod2obspred.
event	the value whose prevalence we want to calculate (e.g. 1, "present", etc.). This argument is ignored if 'model' is provided.
na.rm	logical, whether NA values should be excluded from the calculation. The default is TRUE.

Value

Numeric value of the prevalence of event in the obs vector.

Author(s)

A. Marcia Barbosa

Examples

```
# calculate prevalence from binary vectors:

(x <- rep(c(0, 1), each = 5))

(y <- c(rep(0, 3), rep(1, 7)))

(z <- c(rep(0, 7), rep(1, 3)))

prevalence(x)

prevalence(y)

prevalence(z)

(w <- c(rep("yes", 3), rep("nope", 7)))

prevalence(w, event = "yes")

# calculate prevalence from a model object:

data(rotif.env)

mod <- glm(Abrigh ~ HabitatDiversity + HumanPopulation, family = binomial, data = rotif.env)

prevalence(model = mod)

# same as:
prevalence(obs = rotif.env$Abrigh)
```

---

rangemapSim   *Pairwise similarity between rangemaps*

Description

Calculate pairwise similarity among rangemaps from a matrix of their areas of intersection and union

Usage

```
rangemapSim(rangemap.matrix, total.area,
method = c("Jaccard", "Sorensen", "Simpson", "Baroni"),
diag = FALSE, upper = FALSE, verbosity = 2)
```

Arguments

rangemap.matrix

	a matrix like the one produced by function `pairwiseRangemaps`, containing the areas of pairwise intersection among rangemaps in the lower triangle, individual rangemap areas in the diagonal, and pairwise union areas in the upper diagonal.
total.area	numeric value indicating the total size of the study area, in the same units as the areas in the `rangemap.matrix`. Used only if 'method' uses shared absences (as is the case of "Baroni")
method	character value indicating the similarity index to use. Currently implemented indices are "Jaccard", "Sorensen", "Simpson" and "Baroni". The default is the first one.
diag	logical value indicating if the diagonal of the resulting matrix should be filled
upper	logical value indicating if the upper triangle of the resulting matrix should be filled (symmetrical to the lower triangle)
verbosity	integer number indicating the amount of messages to display.

Details

Distributional relationships among species are commonly determined based on pair-wise (dis)similarities in species' occurrence patterns. Some of the most commonly employed similarity indices are those of Jaccard (1901), Sorensen (1948), Simpson (1960) and Baroni-Urbani & Buser (1976), which are here implemented for comparing rangemaps based on their areas of intersection and union (Barbosa & Estrada, in press).

Value

This function returns a square matrix of pairwise similarities between the rangemaps in 'rangemap.matrix', calculated with the (first) similarity index specified in 'method'.

rarity	*(Fuzzy) rarity*

Description

This function computes the index of species rarity of Real et al. (2006), using either crisp (presence/absence, i.e. ones and zeros) or fuzzy values (e.g. Favourability, between zero and one), for a single species or for several species across a study area. Rarity is like a (potential) richness index in which rarer species have higher weight.

Usage

```
rarity(data, sp.cols = 1:ncol(data), na.rm = TRUE)
```

Arguments

data	a numeric vector, matrix or data frame containing the presence/absence or the Favourability (fuzzy presence) values for the target species.
sp.cols	names or index numbers of the columns of 'data' that contain the species values for which to compute rarity. The default is to use all columns.
na.rm	logical value indicating whether NA values should be removed before the computation.

Details

If the input data include only one species (i.e. a numeric vector or a one-column table, with one value for each locality), rarity is 1 divided by the sum of its values. If the input includes more than one species or column, rarity is the sum of the product of each (fuzzy) presence value by the rarity of the corresponding species, so that rarer species have higher weight in the resulting sum (Real et al. 2006). See also Estrada et al. (2011) for a more complex version of fuzzy rarity.

Value

If 'data' is a vector or a one-column table, or if 'sp.cols' is of length 1, this function returns a single value of rarity for the underlying species, which is simply 1 divided by the sum of its values. If 'data' and 'sp.cols' refer to more than 1 column, the function returns the total combined rarity value of all corresponding species for each row in 'data' (see Examples).

rotif.env   *Rotifers and environmental variables on TDWG level 4 regions of the*
                                   world

Description

These data were extracted from a database of monogonont rotifer species presence records on the geographical units used by the Biodiversity Information Standards (formerly Taxonomic Database Working Group, TDWG: <https://www.tdwg.org>) and a few environmental (including human and spatial) variables on the same spatial units. The original data were compiled and published by Fontaneto et al. (2012) in long (narrow, stacked) format. Here they are presented in wide or un-stacked format (presence-absence table, obtained with the splist2presabs function), reduced to the species recorded in at least 100 (roughly one third) different TDWG level 4 units, and with abbreviations of the species' names (obtained with the spCodes function). Mind that this is not a complete picture of these species' distributions, due to insufficient sampling in many regions.

Usage

```
data(rotif.env)
```

Format

A data frame with 291 observations on the following 47 variables.

TDWG4 a factor with 291 levels indicating the abbreviation code of each TDWG4 region

LEVEL_NAME a factor with 291 levels indicating the name of each TDWG4 region

REGION_NAME a factor with 47 levels indicating the name of the main geographical region to which each TDWG4 level belongs

CONTINENT a factor with 9 levels indicating the continent to which each TDWG4 level belongs

rotifers   *Rotifer species on TDWG level 4 regions of the world*

Description

These data were extracted from a database of monogonont rotifer species records on the geographical units used by the Biodiversity Information Standards (formerly Taxonomic Database Working Group, TDWG: https://www.tdwg.org). The original data were compiled and published by Fontaneto et al. (2012) for all TDWG levels. Here they are reduced to the TDWG - level 4 units and to the species recorded in at least 100 (roughly one third) of these units. Mind that this is not a complete picture of these species' distributions, due to insufficient sampling in many regions.

Usage

```
data("rotifers")
```

Format

A data frame with 3865 observations on the following 2 variables.

TDWG4 a factor with 274 levels corresponding to the code names of the TDWG level 4 regions in which the records were taken

species a factor with 30 levels corresponding to the names of the (sub)species recorded in at least 100 different TDWG level 4 regions

Source

Examples

```
data(rotifers)

head(rotifers, 10)
```

---

selectAbsences   *Select (spatially biased) absence rows.*

Description

This function takes a matrix or data frame containing species presence (1) and absence (0) data, and it selects among the absence rows to stay within a given number or ratio of absences, and/or within and/or beyond a given distance to the presences. Optionally, absences can be selected with higher probability towards the vicinity of presences, to reproduce survey bias.

Usage

```
selectAbsences(data, sp.cols, coord.cols = NULL, min.dist = NULL,
max.dist = NULL, n = NULL, mult.p = NULL, bias = FALSE, bunch = FALSE,
seed = NULL, plot = !is.null(coord.cols), df = TRUE, verbosity = 2)
```

Arguments

data	a matrix or data frame containing, at least, one column with the species' presence (1) and absence (0) records, with localities in rows; and (if distance or spatial bias are required) two columns with the spatial coordinates.
sp.cols	names or index numbers of the columns containing the species presences (1) and absences (0) in 'data'.
coord.cols	names or index numbers of the columns containing the spatial coordinates in 'data' (x and y, or longitude and latitude, in this order). Needed if distance or spatial bias are required.
min.dist	(optional) numeric value specifying the minimum distance (in the same units as 'coord.cols') at which selected absences should be from the presences.
max.dist	(optional) numeric value specifying the maximum distance (in the same units as 'coord.cols') at which selected absences should be from the presences.
n	(optional) integer value specifying the number of absence rows to select. Can also be specified as a ratio – see 'mult.p' below.
mult.p	(optional) numeric value specifying how many times the number of presences to use as 'n' (e.g. 10 times as many absences as presences). Ignored if 'n' is not NULL.
bias	logical value specifying if the selection of absences should be biased towards the vicinity of presences. Requires specifying 'coord.cols'. The default is FALSE. Can take time (and memory) for large datasets.
bunch	[PENDING IMPLEMENTATION] logical value specifying if the selected absences should concentrate around presences in proportion to their local density, as in Vollering et al. (2019). The default is FALSE.
seed	(optional) integer value to pass to set.seed specifying the random seed to use for sampling among the absences.

plot	logical value specifying whether to plot the result. The default is TRUE if 'co-ord.cols' are provided.
df	logical value specifying whether to return a dataframe with the input 'data' after removal of the non-selected absences. The default is TRUE. If set to FALSE, the output is a logical vector specifying if each row of 'data' was selected or not.
verbosity	numeric value indicating the amount of messages to display. Choose 0 for no messages.

Details

Species occurrence data typically incorporate two probability distributions: the actual probability of the species being present, and the probability of it being recorded if it was present (Merow et al. 2013). Thus, any covariation between recording probability and the predictor variables can bias the predictions of species distribution models (Yackulic et al. 2013).

Methods to correct for this bias include the selection of (pseudo)absences preferably towards the vicinity of presence records, in order to reproduce the survey bias. This function implements this latter strategy, in several (alternative or complementary) ways: 1) selecting absences within and/or outside a given distance from presences; 2) biasing the random selection of absences, making it more likely towards the vicinity of presences (providing the 'prob' argument in `sample` with the result of `distPres`); or [PENDING IMPLEMENTATION!] 3) bunching up the absences preferably around the areas with higher densities of presences (Vollering et al. 2019).

Value

This function returns the 'data' input after removal of the non-selected absences, or (if df=FALSE) a logical vector specifying if each row of 'data' was selected or not. If plot=TRUE and provided 'coord.cols', it also plots the presences (blue "plus" signs), the selected absences (red "minus" signs) and the excluded absences (orange dots).

```

---

sharedFav   *Shared favourability for two competing species*

Description

This function implements the graphical analyses of Acevedo et al. (2010, 2012) on biogeographical interactions. It takes two vectors of favourability values at different localities for, respectively, a stronger and a weaker competing species (or two equally strong competitors), and plots their favourableness or shared favourability to assess potential competitive interactions.

Usage

```
sharedFav(strong_F, weak_F, conf = 0.95, bin_interval = "0.1", ...)
```

Arguments

strong_F	a numeric vector of favourability values (obtained, e.g., with functions `Fav` or `multGLM`) for the stronger species.
weak_F	a numeric vector of favourability values for the weaker species. Must be of the same lenght and in the same order as strong_F.
conf	confidence level for the confidence intervals in the plot. The default is 0.95. Set it to NA for no confidence intervals (see "Note" below).
bin_interval	character value specifying the method for grouping the favourability values into bins, to plot and compare mean favourability for each species. Currently implemented options are "0.1" (the default, dividing the values at 0.1 intervals as per Acevedo et al. 2010, 2012) and "quantiles" (as the former method may generate an error if there are overly small bins to calculate confidence intervals). See "Note" below.
...	some additional arguments can be passed to `barplot`, such as "main" (for the plot title) or "las" (for the orientation of the axis labels).

Details

This function implements the biogeographic analyses of Acevedo et al. (2010, 2012), assessing the trends of environmental favourability across a range of favourability intersection values between two interacting species. It first calculates the fuzzy intersection (minimum value) between the two species' favourability values at each locality (i.e., favourability for the occurrence of both species simultaneously); it groups these values into 10 bins; and calculates the mean favourability (and its confidence interval) for each of the two species within each interval.

According to the notion of "favorableness" by Richerson & Lum (1980), competing species may or may not be able to coexist depending on their relative environmental fitnesses; competition between species increases and competitive exclusion decreases as their favourability intersection increases (Acevedo et al. 2010, 2012). The shaded area in the shared favourability plot, where at least one of the species is at intermediate favourability, is the area where competitive interactions may limit species occurrence. Outside this shaded area, where favourability is either very low for at least one of the species (left) or very high for both species (right side of the plot), competition is not limiting (see also `bioThreat` for details).

Value

This function returns the numeric value of the fuzzy overlap index (FOvI; Dubois & Prade 1980, Acevedo et al. 2010, 2012), a data frame with the bin values and the shared favourability plot, with circles and a continuous line representing favourability for the stronger species, and squares and a dashed line representing favourability for the weaker species. The height of the bars at the bottom represents the proportional sample size of each bin.

Note

This function may generate an error if one or more bins don't have enough values for the confidence interval to be computed. If this occurs, you can try a different 'bin_interval' (e.g. "quantiles") or set the 'conf' argument to NA (in which case confidence intervals will not be computed). Either will affect only the plot, not the overall fuzzy overlap value.

simFromSetOps   *Calculate similarity from set operations*

Description

This function calculates pair-wise similarity based on the results of set operations (intersection, union) among the subjects.

Usage

```
simFromSetOps(size1, size2, intersection, union, total.size = NULL,
method = c("Jaccard", "Sorensen", "Simpson", "Baroni"),
verbosity = 1)
```

Arguments

size1	size of subject 1 (e.g., area of the distribution range of a species, or its number of presences within a grid). Not needed if method = "Jaccard".
size2	the same for subject 2.
intersection	size of the intersection among subjects 1 and 2 (area of the intersection among their distribution ranges, or number of grid cells in which they co-occur).
union	size of the union of subjects 1 and 2.
total.size	total size of the study area. Needed only when calculating a similarity index that takes shared absences into account (i.e., method = "Baroni").
method	the similarity index to use. Currently implemented options are "Jaccard", "Sorensen", "Simpson" or "Baroni".
verbosity	integer indicating whether to display messages.

Details

Similarities among ecological communities, beta diversity patterns, biotic regions, and distributional relationships among species are commonly determined based on pair-wise (dis)similarities in species' occurrence patterns. This function implements some of the most commonly employed similarity indices, namely those of Jaccard (1901), Sorensen (1948), Simpson (1960) and Baroni-Urbani & Buser (1976), based on the amount of occupied and overlap area between two species.

Value

The numeric value of similarity among subjects 1 and 2.

simMat   *Pair-wise (fuzzy) similarity matrix*

Description

simMat takes a matrix or data frame containing species occurrence data or regional species com-
position, either categorical (0 or 1) or fuzzy (between 0 and 1), and uses the [fuzSim](#) function to
calculate a square matrix of pair-wise similarities between them, using a fuzzy logic version (Bar-
bosa, 2015) of the specified similarity index.

Usage

```
simMat(data, method, diag = TRUE, upper = TRUE, verbosity = 2)
```

Arguments

data	a matrix or data frame containing (optionally fuzzy) species presence-absence data (in wide format, i.e. one column per species), with 1 meaning presence, 0 meaning absence, and values in between for fuzzy presence (or the degree to which each locality belongs to the set of species presences; see Zadeh, 1965). Fuzzy presence-absence can be obtained, for example, with [multGLM](#), [distPres](#) or [multTSA](#). These data can also be [transpose](#)d for comparing regional species compositions.
method	the similarity index whose fuzzy version to use. See [fuzSim](#) for available op-tions.
diag	logical value indicating whether the diagonal of the matrix should be filled (with ones). Defaults to TRUE.
upper	logical value indicating whether the upper triangle of the matrix (symmetric to the lower triangle) should be filled. Defaults to TRUE.
verbosity	integer value indicating the amount of messages to display; currently meaningful values are 0, 1, and 2 (the default).

Details

The fuzzy versions of species occurrence data and of binary similarity indices introduce tolerance
for small spatial differences in species' occurrence localities, allow for uncertainty about species
occurrence, and may compensate for under-sampling and geo-referencing errors (Barbosa, 2015).

Value

This function returns a square matrix of pair-wise similarities among the species distributions (columns) in `data`. Similarity is calculated with the fuzzy version of the index specified in `method`, which yields traditional binary similarity if the data are binary (0 or 1), or fuzzy similarity if the data are fuzzy (between 0 and 1) (Barbosa, 2015).

spCodes   *Obtain unique abbreviations of species names*

Description

This function takes a vector of species names and converts them to abbreviated species codes containing the specified numbers of characters from the genus, the specific and optionally also the subspecific name. Separators can be specified by the user. The function checks that the resulting codes are unique.

Usage

```
spCodes(species, nchar.gen = 3, nchar.sp = 3, nchar.ssp = 0,
sep.species = " ", sep.spcode = "", verbosity = 2)
```

Arguments

species	a character vector containig the species names to be abbreviated.
nchar.gen	the number of characters from the genus name to be included in the resulting species code.
nchar.sp	the number of characters from the specific name to be included in the resulting species code.
nchar.ssp	optionally, the number of characters from the subspecific name to be included in the resulting species code. Set it to 0 if you have subspecific names in 'species' but do not want them included in the resulting species codes.
sep.species	the character that separates genus, specific and subspecific names in 'species'. The default is a white space.
sep.spcode	the character you want separating genus and species abbreviations in the resulting species codes. The default is an empty character (no separator).
verbosity	integer value indicating the amount of messages to display. Defaults to 2, for showing all messages.

Value

This function returns a character vector containing the species codes resulting from the abbreviation. If the numbers of characters specified do not make for unique codes, an error message is displayed showing which 'species' names caused it, so that you can try again with different 'nchar.gen', 'nchar.sp' and/or 'nchar.ssp'.

substr, strsplit

Examples

```
data(rotifers)

head(rotifers)

## add a column to 'rotifers' with shorter versions of the species names:

## Not run:
rotifers$spcode <- spCodes(rotifers$species, sep.species = "_",
nchar.gen = 1, nchar.sp = 4, nchar.ssp = 0, sep.spcode = ".")
```

```
# this produces an error due to resulting species codes not being unique

## End(Not run)

rotifers$spcode <- spCodes(rotifers$species, sep.species = "_",
nchar.gen = 1, nchar.sp = 5, nchar.ssp = 0, sep.spcode = ".")

# with a larger number of characters from the specific name,
# resulting codes are now unique

## check out the result:
head(rotifers)
```

---

splist2presabs   *Convert a species list to a presence-absence table*

Description

This function takes a locality+species dataset in long (stacked) format, i.e., a matrix or data frame containing localities in one column and their recorded species in another column, and converts them to a presence-absence table (wide format) suitable for mapping and for computing distributional similarities (see e.g. [simMat](#)). Try out the Examples below for an illustration).

Usage

```
splist2presabs(data, sites.col, sp.col, keep.n = FALSE)
```

Arguments

data	a matrix or data frame with localities in one column and species in another column. Type or paste 'data(rotifers); head(rotifers)' (without the quote marks) in the R console for an example.
sites.col	the name or index number of the column containing the localities in 'data'.
sp.col	the name or index number of the column containing the species names or codes in 'data'.
keep.n	logical value indicating whether to get in the resulting table the number of times each species appears in each locality; if FALSE (the default), only presence (1) or absence (0) is recorded.

Value

A data frame containing the localities in the first column and then one column per species indicating their presence or absence (or their number of records if keep.n = TRUE). Type 'data(rotif.env); head(rotif.env[,18:47])' (without the quote marks) in the R console for an example.

sp.col = "species", keep.n = FALSE)

head(rotifers.presabs)
```

---

stepByStep	*Analyse and compare stepwise model predictions*

Description

This function builds a generalized linear model with forward stepwise inclusion of variables, using AIC as the selection criterion, and provides the values predicted at each step, as well as their correlation with the final model predictions.

Usage

```
stepByStep(data, sp.col, var.cols, family = binomial(link = "logit"),
Favourability = FALSE, trace = 0, direction = "forward", k = 2,
cor.method = "pearson")
```

Arguments

data	a data frame containing your target and predictor variables.
sp.col	name or index number of the column of 'data' that contains the response variable.
var.cols	names or index numbers of the columns of 'data' that contain the predictor variables.
family	argument to be passed to the [glm](#) function indicating the family (and error distribution) to use in modelling. The default is binomial distribution with logit link (for binary response variables).
Favourability	logical, whether to apply the [Fav](#)ourability function to remove the effect of prevalence from predicted probability (Real et al. 2006). Applicable only to binomial GLMs. Defaults to FALSE.
trace	argument to pass to the [step](#) function. If positive, information is printed during the stepwise procedure. Larger values may give more detailed information. The default is 0 (silent).

direction   argument to pass to the [step](#) function. Implementation contributed by Alba
                 Estrada. Can be "forward" (the default, for back-compatibility with former ver-
                 sions of 'stepByStep'), "backward", or "both".

k   argument to pass to the [step](#) function indicating the multiple of the number
                 of degrees of freedom used for the penalty. The default is 2, which yields the
                 original AIC. You can use larger values for a more stringent selection– e.g., for
                 a critical p-value of 0.05, use k = qchisq(0.05, 1, lower.tail = F).

cor.method   character string to pass to [cor](#) indicating which coefficient to use for correlating
                 predictions at each step with those of the final model. Can be "pearson" (the
                 default), "kendall", or "spearman".

Details

Stepwise variable selection often includes more variables than would a model selected after ex-
amining all possible combinations of the variables (e.g. with package **MuMIn** or **glmulti**). The
'stepByStep' function can be useful to assess if a stepwise model with just the first few variables
could already provide predictions very close to the final ones (see e.g. Fig. 3 in Munoz et al.,
2005). It can also be useful to see which variables determine the more general trends in the model
predictions, and which variables just provide additional (local) nuances.

Value

This function returns a list of the following components:

predictions   a data frame with the model's fitted values at each step of the variable selection.

correlations   a numeric vector of the correlation between the predictions at each step and
                 those of the final model.

variables   a character vector of the variables in the final model, named with the step at
                 which each was included.

model   the resulting model object.

family = poisson)
```

---

stepwise   *Stepwise regression*

Description

This function runs a stepwise regression, selecting and/or excluding variables based on the significance (p-value) of the statistical tests implemented in the [add1](add1) and drop1 functions of R.

Usage

```
stepwise(data, sp.col, var.cols, id.col = NULL, family = binomial(link="logit"),
direction = "both", test.in = "Rao", test.out = "LRT", p.in = 0.05, p.out = 0.1,
trace = 1, simplif = TRUE, preds = FALSE, Favourability = FALSE, Wald = FALSE)
```

Arguments

data	a data frame (or an object that can be coerced with 'as.data.frame') containing your target and predictor variables.
sp.col	name or index number of the column of 'data' that contains the response variable.
var.cols	names or index numbers of the columns of 'data' that contain the predictor variables.
id.col	(optional) name or index number of column containing the row identifiers (if defined, it will be included in the output 'predictions' data frame).
family	argument to be passed to [glm](glm) indicating the error distribution (and optionally the link function) to be used in the model. The default is binomial distribution with logit link (i.e. logistic regression, for binary response variables), and it is the only one that has been tested so far. If you try other options, please carefully check your results and let me know if you find a bug.
direction	the mode of stepwise search. Can be either "forward", "backward", or "both" (the default).
test.in	argument to pass to [add1](add1) specifying the statistical test whose 'p.in' a variable must pass to enter the model. Can be "Rao" (the default), "LRT", "Chisq" or "F".

test.out	argument to pass to [drop1](#) specifying the statistical test whose 'p.out' a variable must exceed to be expelled from the model (if it does not simultaneously pass the 'test.in' when direction="both"). Can be "LRT" (the default), "Rao", "Chisq" or "F".
p.in	threshold p-value for a variable to enter the model. Defaults to 0.05.
p.out	threshold p-value for a variable to leave the model. Defaults to 0.1.
trace	if positive, information is printed to the console at each step. The default is 1, for naming each variable that was added or removed. With trace=2, the summary of the model at each step is also printed.
simplif	logical, whether to return a simpler output containing only the model object (the default), or a list with, additionally, a data frame with the variable included or excluded at each step.
preds	logical, whether to return also the predictions given by the model at each step. This argument is ignored if simplif=TRUE.
Favourability	logical, whether to convert the predictions (if preds=TRUE) with the [Fav](#) function. This argument is ignored if simplif=TRUE.
Wald	logical, whether to print the Wald test statistics using [summaryWald](#), rather than the z test normally returned by [summary](#). Used only if trace > 1. Requires the **aod** package. The default is FALSE.

Details

Stepwise variable selection is a way of selecting a subset of significant variables to get a simple and easily interpretable model. It is more computationally efficient than best subset selection. This function uses the R functions [add1](#) for selecting and [drop1](#) for excluding variables. The default parameters mimic the "Forward Selection (Conditional)" stepwise procedure implemented in the IBM SPSS software. This is a widely used (e.g. Munoz et al. 2005, Olivero et al. 2017, 2020, Garcia-Carrasco et al. 2021) but also widely criticized method for variable selection (e.g. Harrell 2001; Whittingham et al. 2006; Flom & Cassell, 2007; Smith 2018), though its AIC-based counterpart (implemented in the [step](#) R function) is also not without flaws (e.g. Murtaugh 2014; Coelho et al. 2019).

Value

If simplif=TRUE (the default), this function returns the model object obtained after the variable selection procedure. If simplif=FALSE, it returns a list with the following components:

model	the model object obtained after the variable selection procedure.
steps	a data frame where each row shows the variable included or excluded at each step.
predictions	(if preds=TRUE) a data frame where each column contains the predictions of the model obtained at each step. These predictions are probabilities by default, or favourabilities if Favourability=TRUE.

summaryWald   *Model summary with Wald (instead of z) test statistics*

Description

This function produces a summary of a generalized linear model, with the Wald test (instead of the z test) and associated statistics.

Usage

```
summaryWald(model, interceptLast = TRUE)
```

Arguments

`model`	a model object of class "glm".
`interceptLast`	logical, whether to place the intercept in the last (rasther than the first) row of the output. Defaults to TRUE.

Details

This function requires the **aod** package, whose `wald.test` function is used for computing the Wald test.

Value

This function returns a data frame with the model summary statistics.

timer	*Timer*

Description

Reporting of time elapsed since a given start time. This function is used internally by other functions in the package.

Usage

```
timer(start.time)
```

Arguments

start.time   A date-time object of class `POSIXct`, e.g. as given by `Sys.time`.

Value

The function returns a message informing of the time elapsed since the input 'start.time'.

# see how long it took:
timer(start)
```

---

transpose   *Transpose (part of) a matrix or dataframe*

Description

This function transposes (a specified part of) a matrix or data frame, optionally using one of its columns as column names for the transposed result. It can be useful for turning a species presence-absence table into a regional species composition table.

Usage

```
transpose(data, sp.cols = 1:ncol(data), reg.names = NULL)
```

Arguments

data   a matrix or data frame containing the species occurrence data to transpose.

sp.cols   names or index numbers of the columns containing the species occurrences in 'data' which are meant to be transposed.

reg.names   name or index number of the column in 'data' containing the region names, to be used as column names in the transposed result.

Value

This function returns the transposed 'sp.cols' of 'data', with the column specified in 'reg.names' as column names.

head(rotif.reg)
```

---

triMatInd   *Triangular matrix indices*

Description

This function outputs the indices of one triangle (the lower one by default) of an input square matrix. It is used by [simMat](#) and, for large matrices, makes it faster than e.g. with [lower.tri](#) or [upper.tri](#).

Usage

```
triMatInd(mat, lower = TRUE, list = FALSE)
```

Arguments

mat	a square matrix.
lower	logical indicating whether the indices should correspond to the lower triangle. The default is TRUE; FALSE produces the upper triangle indices.
list	logical indicating whether the results should be output as a list instead of a matrix. The default is FALSE.

Value

The indices (row, column) of the elements of the matrix that belong to the requested triangle.

mat
triMatInd(mat)
triMatInd(mat, list = TRUE)
```

---

vulnerability   *(Fuzzy) vulnerability*

Description

This function computes the index of species vulnerability of Estrada et al. (2011), using either crisp (presence/absence, i.e. ones and zeros) or fuzzy ([Fav]ourability, between zero and one) values, taking into account the conservation status of each species. Vulnerability is like a (potential) richness index in which more vulnerable species (i.e., those with a more threatened conservation status) have higher weight.

Usage

```
vulnerability(data, sp.cols = 1:ncol(data), categories, na.rm = TRUE)
```

Arguments

data	a numeric vector, matrix or data frame containing the presence/absence (ones and zeros) or the [Fav]ourability (fuzzy presence, between zero and one) values for the target species.
sp.cols	names or index numbers of the columns of 'data' that contain the species values for which to compute vulnerability. The default is to use all columns.
categories	numeric vector of the same length as 'sp.cols' (or of length 1 if 'data' is a vector) indicating the IUCN Red List category of each species. This vector should be provided in the same order as the columns in data[, sp.cols]. See Details.
na.rm	logical value indicating whether NA values should be removed before the computation.

Details

The numeric values for the 'categories' argument are suggested by Estrada et al. (2011) to be as follows for each species, according to its IUCN Red List category (available at https://www.iucnredlist.org):

Critically endangered (CR): 16

Endangered (EN): 8

Vulnerable (VU): 4

Near Threatened (NT): 2

Least Concern (LC): 1

Data Deficient (DD): 1

Not evaluated (NE): 0

These values follow an exponential scale, because a critically endangered species is generally considered more important than two endangered species, an endangered species more important than two vulnerable species, and so on (Estrada et al. 2011).

Value

This function returns a numeric vulnerability value for each value or each row in 'data'.
